

## CSE 331 Final Exam Preparation

This is in no way a substitute for exam preparation, merely a compilation of all the key talking points.

Chandra Neppalli

May 5, 2021

# Counter Example

Best proof to use to *disprove* universally true propositions.

# Counter Example

Best proof to use to *disprove* universally true propositions.

Ex: Every day is a Wednesday, where a counter example would be Monday is not Wednesday.

# Contradiction

Best proof to use if you want to assert something is true.

Figure: Sourced from Google

# Contradiction

Best proof to use if you want to assert something is true.

Assume what you want to prove is false, then show this leads to a contradiction.

Figure: Sourced from Google

# Contradiction

Best proof to use if you want to assert something is true.

Assume what you want to prove is false, then show this leads to a contradiction.

Therefore, the original assumption has to be true.

Figure: Sourced from Google

# Contraposition

Best proof for proving causality. Define two propositions E and F.

# Contraposition

Best proof for proving causality. Define two propositions  $E$  and  $F$ .

If you want to prove that  $E \rightarrow F$ , it might be more doable to prove  $\neg F \rightarrow \neg E$ , as they are both logically equivalent.

# Contraposition

Best proof for proving causality. Define two propositions  $E$  and  $F$ .

If you want to prove that  $E \rightarrow F$ , it might be more doable to prove  $\neg F \rightarrow \neg E$ , as they are both logically equivalent.

This is especially useful if the **scope** of  $F$  is smaller than the scope of  $E$ .

# Direct Proof

If the proof is *simple*, consider directly proving it.

# Direct Proof

If the proof is *simple*, consider directly proving it.

Remember though, that you must maintain *W.L.O.G*, that your proof can never be too specific and must be arbitrary.

# Proof by Induction

Proof by Induction is a really nice proof technique when you reduce your proof to a known correct base case.

# Proof by Induction

Proof by Induction is a really nice proof technique when you reduce your proof to a known correct base case.

If proof needs to be correct for all numbers  $\in \mathbb{N}$ , and each step is dependant on the previous step, then *every* step can be reduced to a definitive base case that is easy to directly prove.

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

- $P(0) = I$

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

- $P(0) = I$
- $P(i)$  is an accumulator. This means that  $P(i + 1) > P(i)$

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

- $P(0) = I$
- $P(i)$  is an accumulator. This means that  $P(i + 1) > P(i)$
- $\forall i, P(i) \leq k$

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

- $P(0) = l$
- $P(i)$  is an accumulator. This means that  $P(i + 1) > P(i)$
- $\forall i, P(i) \leq k$

From these 3 properties, the number of iterations is bounded by  $k - l + 1$

# Extra: Progress Measure

This is useful for proving an algorithm with a loop terminates.

Let  $P(i)$  denote an integer such that:

- $P(0) = l$
- $P(i)$  is an accumulator. This means that  $P(i + 1) > P(i)$
- $\forall i, P(i) \leq k$

From these 3 properties, the number of iterations is bounded by  $k - l + 1$

Note: This isn't a runtime analysis, rather a proof that the algorithm terminates.

# Greedy Stays Ahead

This technique is used to prove that a greedy algorithm returns an optimal solution.

Figure: Sourced from New Grounds

# Greedy Stays Ahead

This technique is used to prove that a greedy algorithm returns an optimal solution.

At every step of a greedy algorithm, it will stay *at least* as far as the optimal solution at that step.

Figure: Sourced from New Grounds

# Greedy Stays Ahead

This technique is used to prove that a greedy algorithm returns an optimal solution.

At every step of a greedy algorithm, it will stay *at least* as far as the optimal solution at that step.

HW4 “Attack on Alarms” and Interval Scheduling are examples of problems with greedy solutions.

Figure: Sourced from New Grounds

# Introduction

Let's say there are two groups: Group A and Group B.

# Introduction

Let's say there are two groups: Group A and Group B.

How do we generate a **stable** matching between each member of the two groups efficiently?

# Introduction

Let's say there are two groups: Group A and Group B.

How do we generate a **stable** matching between each member of the two groups efficiently?

Moreover, what is a **stable** matching?

# Perfect Matchings

A **perfect matching** is a bijective matching between A and B.

# Perfect Matchings

A **perfect matching** is a bijective matching between A and B.

**Every member** in group A is matched with exactly one member in group B.

# Perfect Matchings

A **perfect matching** is a bijective matching between A and B.

**Every member** in group A is matched with exactly one member in group B.

Conversely, every member in group B is matched with **exactly** one member in group A.

# Perfect Matchings

A **perfect matching** is a bijective matching between A and B.

**Every member** in group A is matched with exactly one member in group B.

Conversely, every member in group B is matched with **exactly** one member in group A.

With  $n$  members in each group, there are  $n!$  perfect matchings.

# Instability

For a particular matching, define a member  $m$  from group A and  $n$  from group B such that  $(m, n)$  is not in the matching.

# Instability

For a particular matching, define a member  $m$  from group A and  $n$  from group B such that  $(m, n)$  is not in the matching.

If  $m$  prefers  $n$  over their current matching **and**  $n$  prefers  $m$  over their current matching, then  $(m, n)$  is an instability to the perfect matching.

# Stable Matching

A stable matching **is** a perfect matching with no instabilities.

# Stable Matching

A stable matching **is** a perfect matching with no instabilities.

It therefore follows that the number of stable matchings is *at most* the number of perfect matchings, or  $n!$

# Stable Matching

A stable matching **is** a perfect matching with no instabilities.

It therefore follows that the number of stable matchings is *at most* the number of perfect matchings, or  $n!$

The Gale Shapely Algorithm is an  $O(n^3)$  time algorithm that can output a stable matching.

# Stable Matching

A stable matching **is** a perfect matching with no instabilities.

It therefore follows that the number of stable matchings is *at most* the number of perfect matchings, or  $n!$

The Gale Shapely Algorithm is an  $O(n^3)$  time algorithm that can output a stable matching.

With the right data structures, the runtime can be reduced to  $O(n^2)$ .

# Stable Matching

A stable matching **is** a perfect matching with no instabilities.

It therefore follows that the number of stable matchings is *at most* the number of perfect matchings, or  $n!$

The Gale Shapely Algorithm is an  $O(n^3)$  time algorithm that can output a stable matching.

With the right data structures, the runtime can be reduced to  $O(n^2)$ .

Even though the runtime isn't linear, because the input size is  $2n^2 \rightarrow \Theta(n^2)$ <sup>1</sup>, the runtime **with respect** to the input size is  $O(N)$ , or linear time.

---

<sup>1</sup>This comes from  $n$  Group A members and  $n$  Group B members with their  $2n$  preference lists

# Stable Matching

Code:

---

```
Initially all  $m \in M$  and  $w \in W$  are free
While there is a man  $m$  who is free and hasn't proposed to every
woman
    Choose such a man  $m$ 
    Let  $w$  be the highest-ranked woman in  $m$ 's
        preference list to whom  $m$  has not yet proposed
    If  $w$  is free then
         $(m, w)$  become engaged
    Else  $w$  is currently engaged to  $m'$ 
        If  $w$  prefers  $m'$  to  $m$  then
             $m$  remains free
        Else  $w$  prefers  $m$  to  $m'$ 
             $(m, w)$  become engaged
             $m'$  becomes free
        Endif
    Endif
Endwhile
Return the set  $S$  of engaged pairs.
```

# What are graphs?

Graphs are a way to represent relations between data points.

Figure: Sourced from Youtube

# What are graphs?

Graphs are a way to represent relations between data points.

Graphs have a set of vertices which represent data points and a set of edges to model the **relation** between vertices.

Figure: Sourced from Youtube

# What are graphs?

Graphs are a way to represent relations between data points.

Graphs have a set of vertices which represent data points and a set of edges to model the **relation** between vertices.

An edge exists between two or more vertices *iff* there is a connection between them.

Figure: Sourced from Youtube

# Graph Representation

Adjacency List: Keep a  $n$  length array. Vertices are indices of the array where each element of the array contains a pointer to a list of adjacent vertices to the index/vertex. This takes up  $\Theta(n + m)$  space for  $m$  edges.

Adjacency Matrix: Keep a  $n \times n$  matrix. Rows and columns are vertices. An edge  $(u, v)$  exists if the matrix at row  $u$  and column  $v$  is not null This takes up  $\Theta(n^2)$  space.

# Undirected vs. Directed Graphs

A graph is undirected if edges go both ways. If for any vertices  $u$ ,  $v$ , vertex  $u$  connects to  $v$ ,  $v$  connects to  $u$ .

# Undirected vs. Directed Graphs

A graph is undirected if edges go both ways. If for any vertices  $u$ ,  $v$ , vertex  $u$  connects to  $v$ ,  $v$  connects to  $u$ .

A graph is directed if there is an edge  $(u, v)$  such that  $u$  is connected to  $v$ , but  $v$  is not connected to  $u$ .

# Undirected vs. Directed Graphs

A graph is undirected if edges go both ways. If for any vertices  $u$ ,  $v$ , vertex  $u$  connects to  $v$ ,  $v$  connects to  $u$ .

A graph is directed if there is an edge  $(u, v)$  such that  $u$  is connected to  $v$ , but  $v$  is not connected to  $u$ .

A graph is a tree if it is connected and there are **no** cycles present.

# Undirected vs. Directed Graphs

A graph is undirected if edges go both ways. If for any vertices  $u$ ,  $v$ , vertex  $u$  connects to  $v$ ,  $v$  connects to  $u$ .

A graph is directed if there is an edge  $(u, v)$  such that  $u$  is connected to  $v$ , but  $v$  is not connected to  $u$ .

A graph is a tree if it is connected and there are **no** cycles present.

Bus transportation routes could be classified as an undirected graph, while airports and flights could be modeled as a directed graph.

# Paths and Cycles

A path is a sequence of vertices and edges.

# Paths and Cycles

A path is a sequence of vertices and edges.

A cycle is a sequence of vertices and edges where the first and last vertex are **the same**.

# Paths and Cycles

A path is a sequence of vertices and edges.

A cycle is a sequence of vertices and edges where the first and last vertex are **the same**.

A **simple path** is a path that contains no cycles. A **simple cycle** is a cycle in which the only repeating vertices are the first and last.

# Paths and Cycles

A path is a sequence of vertices and edges.

A cycle is a sequence of vertices and edges where the first and last vertex are **the same**.

A **simple path** is a path that contains no cycles. A **simple cycle** is a cycle in which the only repeating vertices are the first and last.

A cycle needs **at least** 4 elements. The **maximum length** of a simple path for a graph with  $n$  vertices is  $n - 1$ <sup>1</sup>.

---

<sup>1</sup>Pigeonhole Principle

# Connectivity

A graph is connected if there is a path between any two vertices.

# Connectivity

A graph is connected if there is a path between any two vertices.

A **directed** graph is *strongly connected* iff for any two vertices  $u$  and  $v$ , if there is a path from  $u$  to  $v$ , there must also be a path from  $v$  to  $u$ .

# Connectivity

A graph is connected if there is a path between any two vertices.

A **directed** graph is *strongly connected* iff for any two vertices  $u$  and  $v$ , if there is a path from  $u$  to  $v$ , there must also be a path from  $v$  to  $u$ .

A directed acyclic graph  $\Leftrightarrow$  topological ordering, meaning the vertices can be ordered in a way that all edges point in the **same** direction.

# Connectivity

A graph is connected if there is a path between any two vertices.

A **directed** graph is *strongly connected* iff for any two vertices  $u$  and  $v$ , if there is a path from  $u$  to  $v$ , there must also be a path from  $v$  to  $u$ .

A directed acyclic graph  $\Leftrightarrow$  topological ordering, meaning the vertices can be ordered in a way that all edges point in the **same** direction.

A graph can be considered  $k$ -partite if its set of vertices can be partitioned into  $k$  subsets where every edge “bridges” 2 different subsets.

# Connectivity

Breadth First Search (BFS) traverses a graph by layers and builds a BFS tree.

# Connectivity

Breadth First Search (BFS) traverses a graph by layers and builds a BFS tree.

It runs in  $\Theta(n + m)$  time and is linear with respect to its input size.

# Connectivity

Breadth First Search (BFS) traverses a graph by layers and builds a BFS tree.

It runs in  $\Theta(n + m)$  time and is linear with respect to its input size.

Depth First Search (DFS) traverses a graph by picking a point and following it until a dead end.

# Interval Scheduling Problem

Given a set of tasks to do over a period in time, how do you pick the **maximum** number of tasks that aren't in conflict?

# Interval Scheduling Problem

Given a set of tasks to do over a period in time, how do you pick the **maximum** number of tasks that aren't in conflict?

One greedy solution is to sort the set of tasks by their earliest → latest finishing time.

# Minimum Spanning Tree Problem

Given a **weighted**, graph, how do you construct a tree such that the accumulation of all the weights in the tree is minimized?

# Minimum Spanning Tree Problem

Given a **weighted**, graph, how do you construct a tree such that the accumulation of all the weights in the tree is minimized?

There are numerous greedy algorithms to generate an MST:

Refer to the sources for proof of correctness and runtime analysis.

# Shortest Path Problem

Given a weighted graph with **no** negative weights, how do you find the shortest path?

# Shortest Path Problem

Given a weighted graph with **no** negative weights, how do you find the shortest path?

The answer is Dijkstra's Algorithm.

# Shortest Path Problem

Given a weighted graph with **no** negative weights, how do you find the shortest path?

The answer is Dijkstra's Algorithm.

Dijkstra's Algorithm is a greedy algorithm that greedily selects the **shortest path** from a source vertex  $s$  to any vertex in the graph.

# Shortest Path Problem

Given a weighted graph with **no** negative weights, how do you find the shortest path?

The answer is Dijkstra's Algorithm.

Dijkstra's Algorithm is a greedy algorithm that greedily selects the **shortest path** from a source vertex  $s$  to any vertex in the graph.

It's proof of correctness and runtime analysis follows from the embedded link.
